

# LookML Developer II Webinar

Looker Training  
2021

Google Cloud

# Good morning, I'm Emma

**Technical Writer**

Looker Documentation

Santa Cruz, CA

# Agenda

## Looker Developer Bootcamp

01

Customizing Looker with Liquid

02

Templated Filters and Parameters

03

Caching & Datagroups

04

Derived Tables

**Examples are based on  
hypothetical data.**

# Why customize with advanced features?

Out of the box, Looker comes equipped with a wide variety of advanced features. Knowing how to use them will help you:

- Create **one-click workflows** between Looker and other tools
- Design highly-reusable code **tailored to individual users needs**

# Why customize with advanced features?

Out of the box, Looker comes equipped with a wide variety of advanced features. Knowing how to use them will help you:

- **Optimize** the query load sent to your database and query runtimes
- Develop rich, **complex analytics** that go beyond basic dimensions and measures

# Customizing with Liquid

# Creating a dynamic Looker experience

Liquid and Looker are a powerful combination. Together, they can:

- Create one-click workflows from Looker to other tools
- Guide a user to relevant, curated content
- Customize how data is displayed in Looker

# What is Liquid?

Open-source, Ruby-based template language created by Shopify. Used in conjunction with LookML to build more flexible, dynamic code.

Liquid code is denoted by braces `{ }`

# What is Liquid?

Liquid falls into three different categories:

- **Objects:** tell Liquid where to show content on a page

```
dimension: product_image {  
  sql: ${product_id} ;;  
  html:  ;;  
}
```

- **Tags:** Create the logic and control flow for templates
- **Filters:** Change the output of a Liquid object

# Using Liquid in Looker

There are several places in LookML where Liquid can be used:

- the `action` parameter
- the `html` parameter
- the `label` parameter of a field
- the `link` parameter
- parameters that begin with `sql`
  - `sql`
  - `sql_on`
  - `sql_table_name`

# Common use cases

Some of the most popular use cases include:

- Creating dynamic links or rendering dynamic images
- Setting up custom drills
- Adding custom conditional formatting
- Integrating templated filters and parameters

# Liquid parameters: Referencing LookML objects

| Variable         | Definition  | Example output   |
|------------------|---|--|
| value            | Field value returned by the database query                | 8521935  |
| rendered_value   | Field value with Looker's default formatting              | \$8,521,935.00   |
| filterable_value | Field value formatted for use as a filter in a Looker URL | 8521935  |
| link             | URL to Looker's default drill link                        | /explore/thelook/orders?fields=orders.order_amount&limit=500 |
| linked_value     | Field value with Looker's default formatting and linking  | <a href="#">\$8,521,935.00</a>                               |

# Custom links

# Custom links: Building workflows

Set up custom workflows between Looker content or between Looker and other internal or external resources.

- Link from an executive dashboard to a detail dashboard
- Link from a Look or dashboard to an Explore
- Link from a value in a Look or dashboard to a related page on the external web (i.e., a Salesforce page)

# The `link` parameter

Most links are added to dimensions and measures using the `link` parameter

- `label` is the name this link will have in the drill menu
- `url` is the link URL and supports full Liquid (but not full HTML)

```
dimension: field_name {  
  link: {  
    label: "desired label name"  
    url: "desired_url"  
    icon_url: "url_of_an_image_file"  
  }  
}
```

- `icon_url` is the image URL to be used as an icon for this link

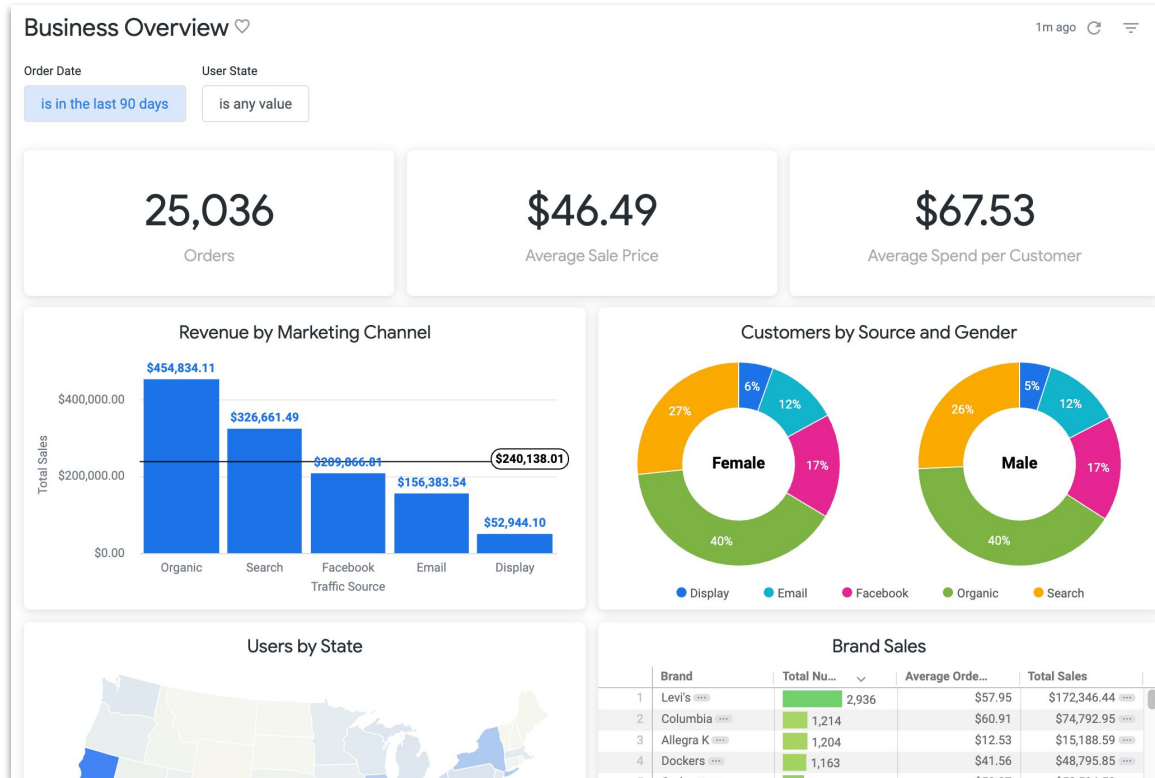

# Linking within Looker

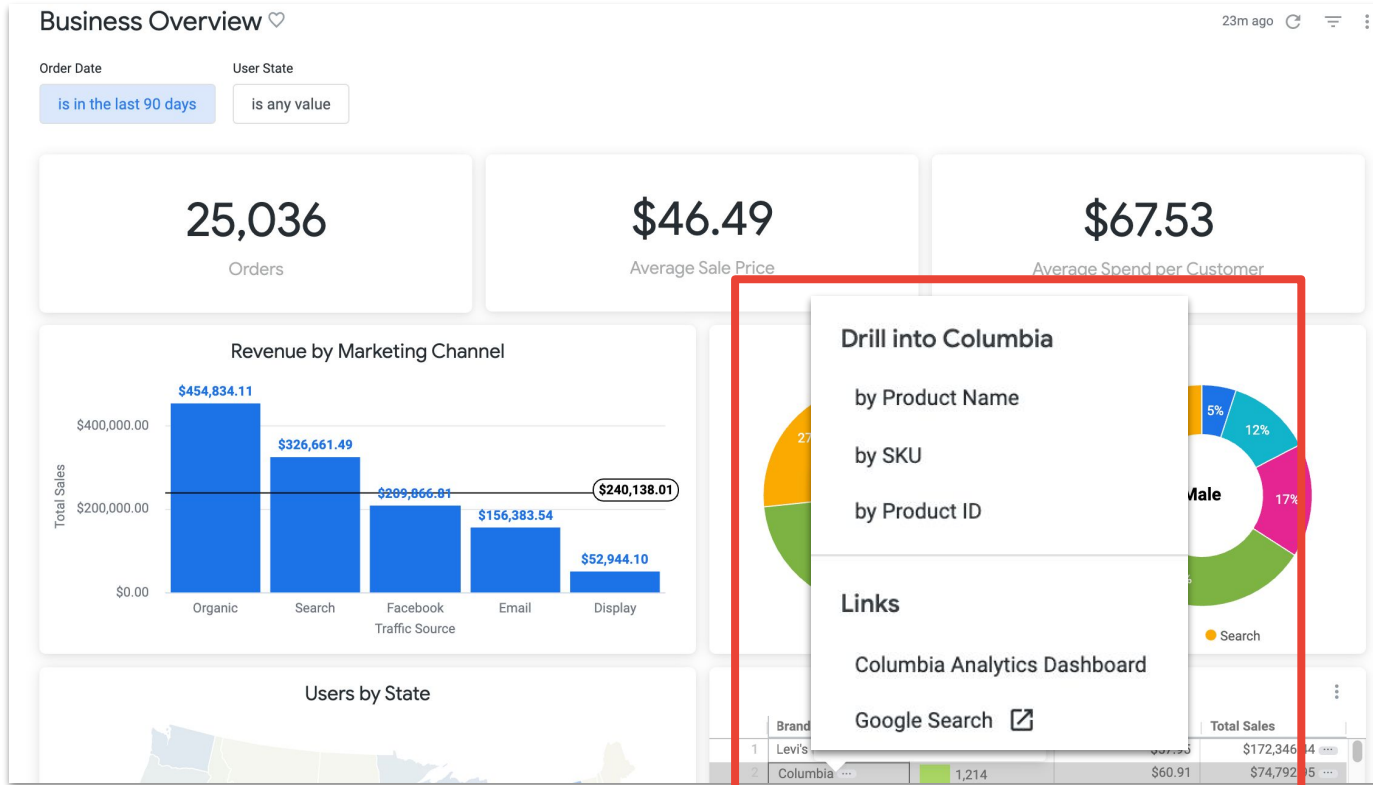

# Linking within Looker

Links between related dashboards and Explores help users navigate with ease. Pre-populated filters allow you to guide their experience.

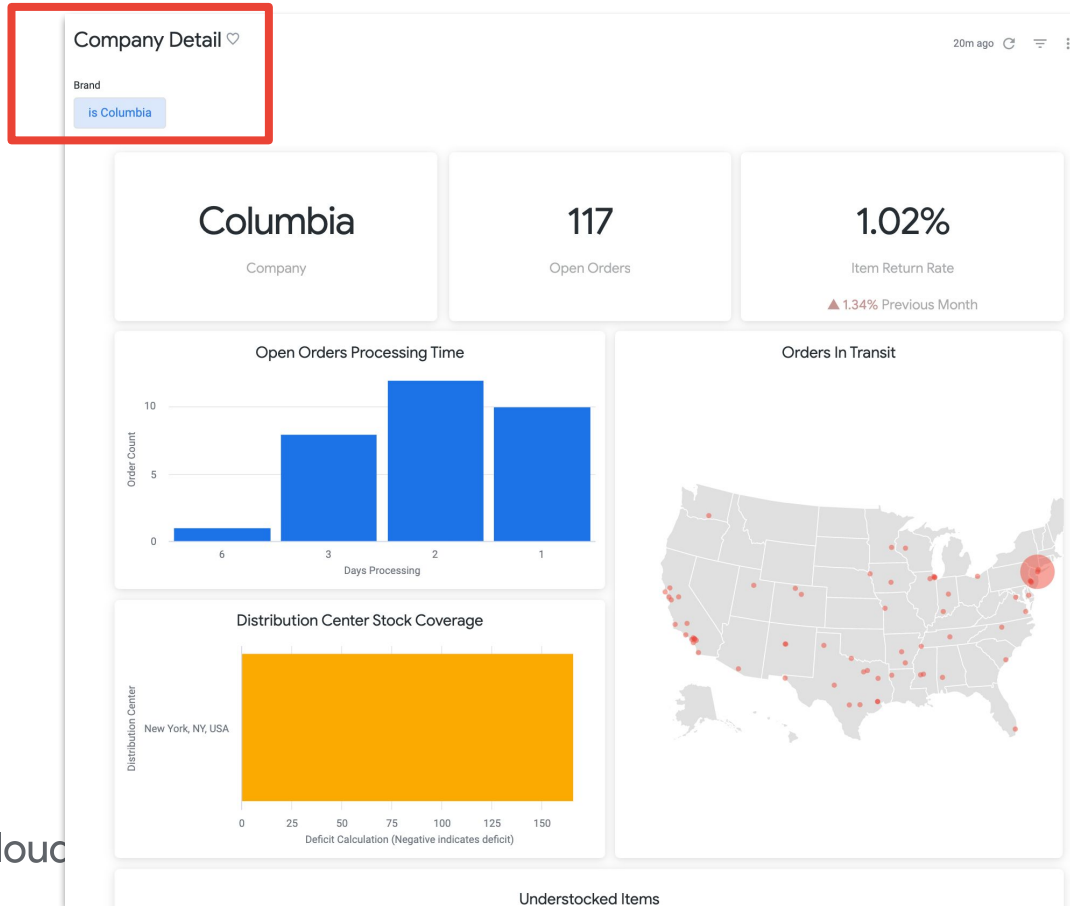

# Linking to a detail dashboard

# Linking to a detail dashboard

# Linking to a detail dashboard

## Links to a dashboard

The **Brand** dimension will contain a link to a Looker dashboard that has been filtered for that brand.

```
dimension: brand {  
  type: string  
  sql: ${TABLE}.brand ;;  
}
```

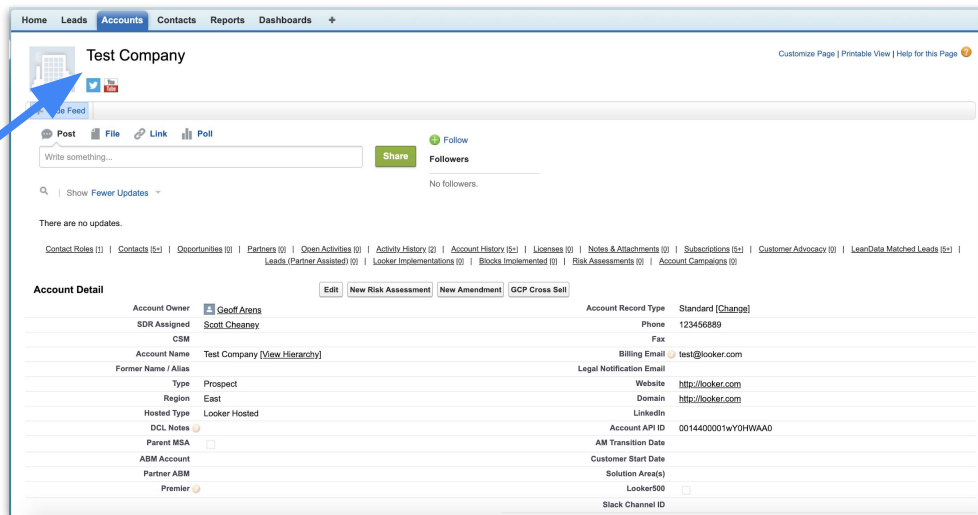

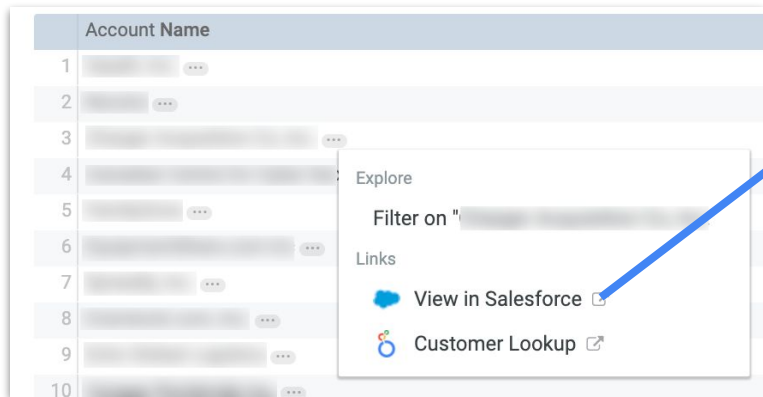

# Links to a dashboard

The **Brand** dimension will contain a link to a Looker dashboard that has been filtered for that brand.

```
dimension: brand {  
  Type: string  
  sql: ${TABLE}.brand ;;  
  link: {  
    label: "{{value}} Analytics Dashboard"  
    url: "/dashboards/24?Brand={{ value | encode_uri }}"  
    icon_url: "http://www.looker.com/favicon.ico"  
  }  
}
```

# Linking outside of Looker

Linking to sources outside of Looker can help build workflows for users. Clicking into a dimension could create a JIRA ticket, run a Google search, or open the corresponding page in Salesforce.

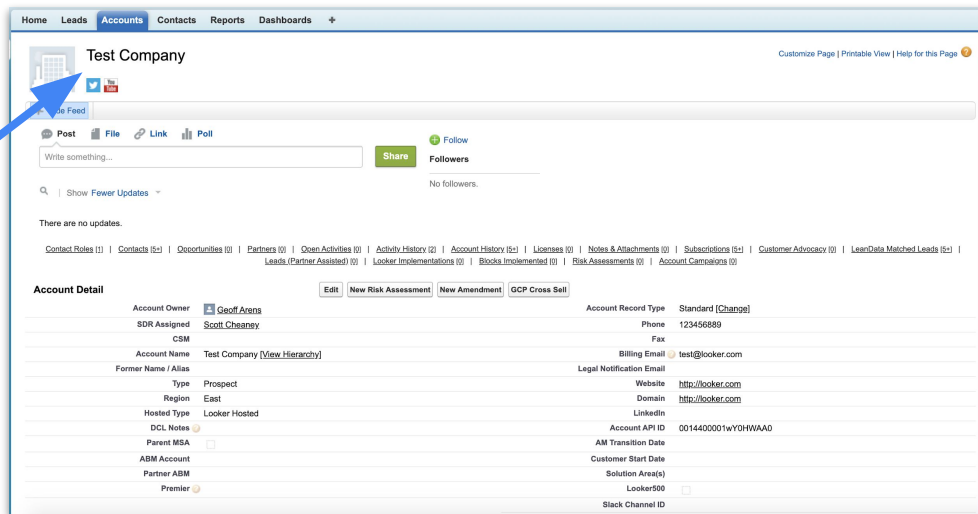

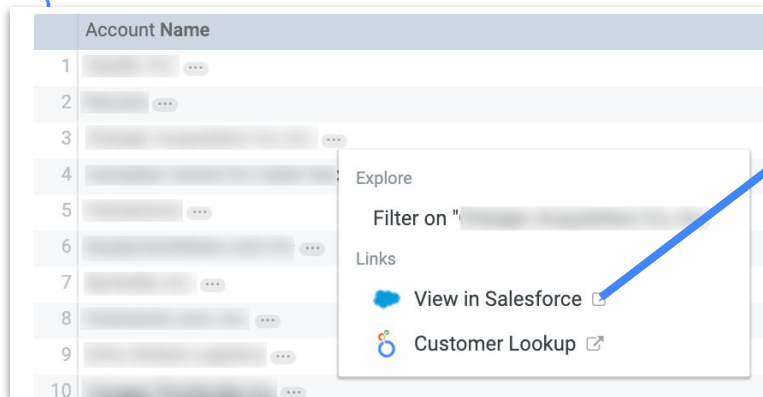

# The `html` parameter

For even more customized drilling and linking, use the [html](#) parameter

- The dimension value will be shown in Looker and will also be a hyperlink
- Clicking the value will take a user to the specified link within the HTML
- Additional adjustments can be made to customize the user experience

# Custom link to Salesforce

```
dimension: id {  
  sql: ${TABLE}.opportunity_id ;  
  html: <a href="https://na9.salesforce.com/{{ value }}" target="_new">  
    </a>  
};
```

# Custom drills

# What is drilling?

Drills allow you to go from high-level metrics like sums and counts into the row-level data that goes into those calculations.

This has the benefit of showing general trends, while also allowing deeper dives to find outliers that may not surface at the high-level.

# What is drilling?

A great place to start is to talk to your users and ask what questions come up when viewing reports.

- What is the next question they have after seeing a number?
- Do certain visualizations always lead them to ask iterative questions?
- What values do they think might have contributed to a number that they'd like to confirm?

# What is drilling?

Designing your drills with these questions in mind will improve your users experience and help them tell better stories from the data.

# Custom drilling with HTML

|   | Name             | Created Date | History        | Total Sales |

# Custom drilling with HTML

```
dimension: history {  
  sql: ${TABLE}.user_name ;;  
  html: <a  
href="/explore/thelook/orders?fields=orders.detail*&f[users.id]  
={{ id._value }}">Orders</a>  
  | <a  
href="/explore/thelook/order_items?fields=order_items.detail*&f  
[users.id]={{ id._value }}">Items</a>;;
```

# Conditional formatting

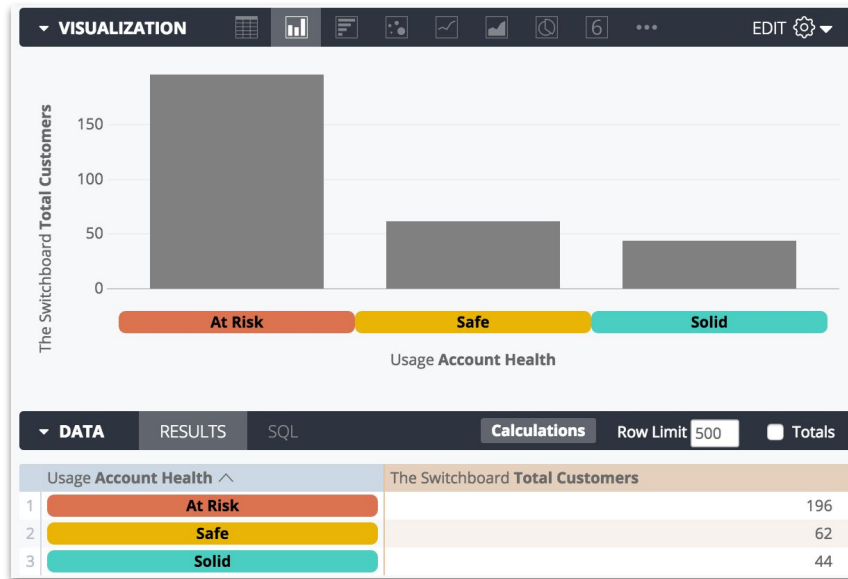

# Conditional formatting

HTML can be used to apply custom formatting to any fields in Looker.

- Add custom colors to dimension labels or header backgrounds
- Include picture or icons as part of displayed values
- Add custom details via a drop down into the cell of a table
- Build a progress bar into the cell of a table that compares the cell value against a goal

# Conditional formatting: Example

```
dimension: account_health {  
  sql: ${TABLE}.account_health ;;  
  html: {% if value == 'At Risk' %}  
    <b><p style="color: black;  
background-color: #dc7350; margin: 0;  
border-radius: 5px; text-align:center">{{ value  
}}</p></b>  
  
{% elsif value == 'Safe' %}  
  <b><p style="color: black;  
background-color: #e9b404; margin: 0;  
border-radius: 5px; text-align:center">{{ value  
}}</p></b>  
  
{% else %}  
  <b><p style="color: black;  
background-color: #49cec1; margin: 0;  
border-radius: 5px; text-align:center">{{ value  
}}</p></b>  
{% endif %}  
  ;;  
}
```

# Conditional formatting: Advanced example

```
measure: total_gross_margin {  
  type: sum  
  value_format_name: usd  
  sql: ${gross_margin} ;;  
}
```

html:

```
<div style="width:100%"> <details>  
<summary style="outline:none">{{ total_gross_margin._linked_value }}  
</summary> Sale Price: {{ total_sales_price._linked_value }}  
<br/>  
Inventory Costs: {{ inventory_items.total_cost._linked_value }}  
</details>  
</div>;;  
}
```

| Order Items Created Year <      |   | 2016  |
|---------------------------------|---|---|
| Order Items Created Month Num ^ |   | Order Items Total Gross Margin  |
| 1                               | 1 | ▼ \$153,275.68<br>Sale Price: \$290,816.84<br>Inventory Costs: \$137,541.15 |
| 2                               | 2 | ▶ \$149,192.79  |
| 3                               | 3 | ▶ \$161,288.00  |
| 4                               | 4 | ▶ \$162,927.63  |
| 5                               | 5 | ▶ \$167,593.41  |
| 6                               | 6 | ▶ \$167,510.27  |

# Conditional formatting: Advanced example

The screenshot shows a Looker dashboard interface. At the top, there is a navigation bar with the Looker logo and menu items: 'Browse', 'Explore', 'Develop', and 'Admin'. Below this, the breadcrumb path is '> Emma Ware Campaign Dashboard' with a heart icon. On the right side of the dashboard header, there is a search icon, a help icon, a user profile icon, and a timestamp '23m ago' next to an 'Edit' button and a settings gear icon.

The main content area features a large horizontal bar with a gradient background transitioning from purple on the left to red on the right. The text is centered and reads:

- Day of campaign:** 43 / 90
- 68% of Goal*
- 2,310,054 Total Events

Below the main bar, there are three event counts with icons:

- f** 317,578 Events
- Q** 622,282 Events
- 🍃** 967,374 Events

A vertical ellipsis menu icon is visible in the top right corner of the main bar.

# Parameters & Templated Filters

# Parameters & Templated Filters

Increase interactivity in Explores, Looks, and Dashboards for users

# Parameters & Templated Filters

**WHAT:** User-input values that can be added into a query dynamically

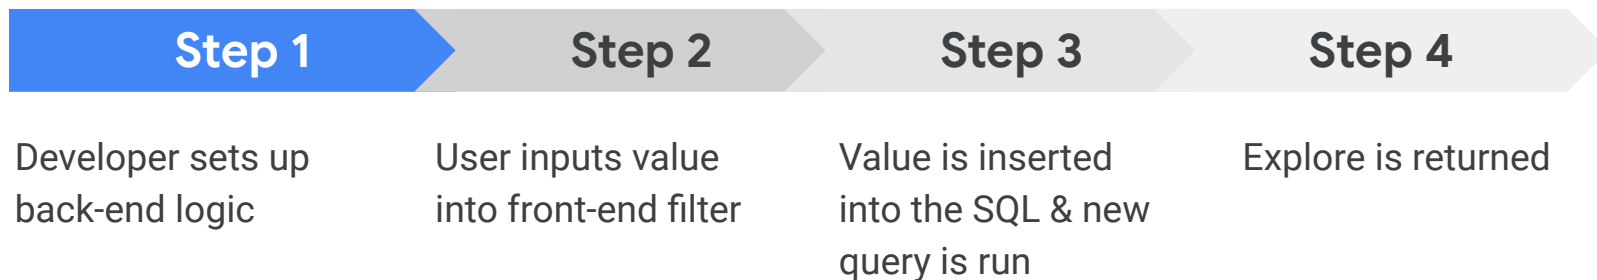

- Parameters: **specific, fixed values** that can be entered by users and then passed directly into a SQL query using liquid
- Templated Filters: user-entered values that are passed into SQL queries using **intelligently written conditional logic**

# Parameters & Templated Filters

**WHY:** Provide **greater flexibility** in how user inputs can influence the SQL queries written

- Dynamic dimensions and measures to consolidate code
- Dynamic derived tables
- Conditionally displayed values

# How Do We Do This in Looker?

# Parameters

# Step 1

Developer Sets Up Back-End Logic

## Step 1

Parameter field that takes a single user-input value

- type: string / number / unquoted / date, etc.
- allowed\_value or suggestions

Used in the syntax

```
{% parameter parameter_name %}
```

```
parameter: field_to_select {  
  type: unquoted  
  allowed_value: {  
    value: "Category"  
    label: "Category"  
  }  
  allowed_value: {  
    value: "Conservation_status"  
    label: "Conservation Status"  
  }  
  allowed_value: {  
    value: "Common_names"  
    label: "Common Names"  
  }  
}  
  
dimension: dynamic_column_select {  
  type: string  
  sql: ${TABLE}.${% parameter field_to_select %} ;;  
  label_from_parameter: field_to_select  
}
```

# Step 2

User Inputs Value into Front-End Filter

Parameters create filter-only field on the front end in an Explore allowed\_values appear as drop-down options

The screenshot shows a data exploration interface with the following components:

- FILTERS (1)**: A section with a "Custom Filter" toggle. It contains a filter configuration for "Species Field to Select" with the value "is". A dropdown menu is open, showing "Conservation Status" (selected with a checkmark), "Common Names", and "Category".
- VISUALIZATION**: A section with a right-pointing arrow.
- DATA**: A section with tabs for "RESULTS" and "SQL". The "SQL" tab is active, showing a query with a "Calculations" button, "Row Limit" set to 500, and a "Totals" toggle.
- SQL Query**:

```
SELECT
  species.Conservation_Status AS species_dynamic_table_reference
FROM biodiversity_in_parks.parks AS parks
LEFT JOIN biodiversity_in_parks.species AS species ON parks.Park_Name = species
.Park_Name

GROUP BY 1
ORDER BY 1
LIMIT 500
```

# Step 3

Value Inserted into SQL & New Query Run

Parameter value is inserted into the  
{% parameter parameter\_name  
%} portion of SQL

```
SELECT
  species.Conservation_Status AS species_dynamic_table_reference
FROM biodiversity_in_parks.parks AS parks
LEFT JOIN biodiversity_in_parks.species AS species ON parks.Park_Name = species
.Park_Name

GROUP BY 1
ORDER BY 1
LIMIT 500
```

# Step 4

Explore is Returned

Step 4

5,000 rows · from cache · 28m ago Run ⚙️

**FILTERS (1)** Custom Filter

⚙️ Species Field to Select  ⌵  ⌵ ✕

**VISUALIZATION** 📊 📈 📄 📊 📄 📊 📈 📄 📊 6 ⋮ EDIT ⚙️

|   | Species                   | Common Names |
|---|---------------------------|--------------|
| 1 | 'A'O, Newell's Shearwater |              |
| 2 | 'Akole                    |              |
| 3 | 'Anaunau, Kunana, Naunau  |              |
| 4 | 'Golden Sedge             |              |
| 5 | 'I 'O Nui, Laukahi        |              |

# Parameters

Example

There's a hierarchy within the product view, and dashboard users need to view dashboard visualizations by any level of this hierarchy. The hierarchy includes the following fields:

- Department (highest level)
- Category
- Brand (lowest level)

# Parameters

Set Up Input Logic via LookML

**label:** what the user will see in the filter options

**value:** the value that will be inserted into the SQL query

**default\_value:** the value that will be inserted automatically if a user has not yet made a selection

```
parameter: select_product_detail
{
  type: unquoted
  default_value: "department"
  allowed_value: {
    value: "department"
    label: "Department"
  }
  allowed_value: {
    value: "category"
    label: "Category"
  }
  allowed_value: {
    value: "brand"
    label: "Brand"
  }
}
```

# Parameters

## Dynamic Dimension Creation

Input the parameter value directly into the SQL as the field name:

dimension: product\_hierarchy {

label\_from\_parameter:

select\_product\_detail

type: string

sql:

```
`${TABLE}`.{% parameter select_product_detail %}
```

```
;;
```

A screenshot of a BI tool interface. At the top, there is a 'FILTERS (1)' section with a 'Custom Filter' toggle. A filter is applied: 'Products Select Product Detail' is set to 'is' and 'Category'. Below this is a 'VISUALIZATION' section with tabs for 'DATA', 'RESULTS', and 'SQL'. The 'SQL' tab is active, showing a query with a red box around the filter parameter and a red arrow pointing to the corresponding alias in the SQL query: 'products.category AS "product\_hierarchy"'. The full SQL query is: 'SELECT products.category AS "product\_hierarchy" FROM public.order\_items AS order\_items LEFT JOIN public.inventory\_items AS inventory\_items ON order\_items.inventory\_item\_id = inventory\_items.id LEFT JOIN public.products AS products ON inventory\_items.product\_id = products.id GROUP BY 1 ORDER BY 1 LIMIT 500'. The interface also shows 'Calculations', 'Row Limit 500', and 'Totals' options.

# Parameters

## Dynamic Dimension Creation

```
dimension: product_hierarchy {  
    label_from_parameter:  
        select_product_detail  
    type: string  
    sql:  
        {% if select_product_detail._parameter_value == 'department' %}  
        ${department}  
        {% elsif select_product_detail._parameter_value == 'category' %}  
        ${category}  
        {% else %}  
        ${brand}  
        {% endif %} ;;  
}
```

# Templated Filters

# Step 1

Developer Sets Up Back-End Logic

## Step 1

Filter field that utilizes Looker's generated SQL filter logic with string, number, date, etc types

Value generates logic in SQL

Used in the syntax

```
{% condition filter_name %}  
field_to_affect {% endcondition %}
```

```
filter: animal_conservation_status {  
  type: string  
  suggest_dimension: species.conservation_status  
  suggest_explore: parks  
}
```

# Step 2

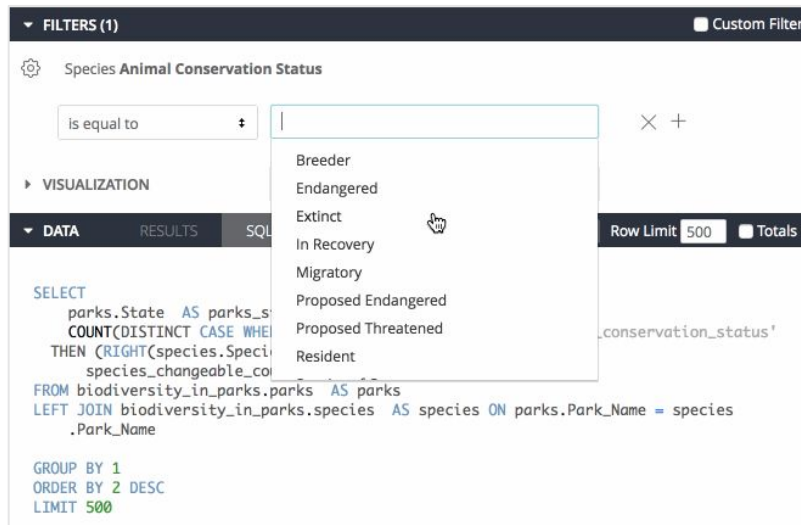

User Inputs Value into Front-End Filter

## Step 2

A filter-only field is created on the front end in an Explore

suggest\_dimension values appear as drop-down options

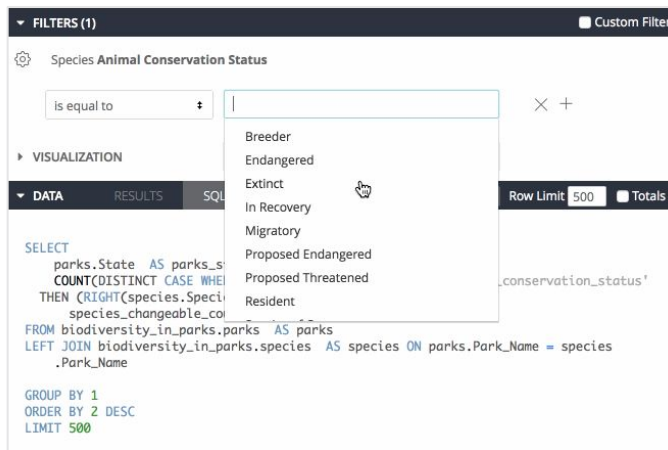

The screenshot shows a web interface for configuring a filter. At the top, it says 'FILTERS (1)' and 'Custom Filter'. Below that, the filter is named 'Species Animal Conservation Status'. The filter type is set to 'is equal to'. A dropdown menu is open, showing a list of conservation status options: Breeder, Endangered, Extinct, In Recovery, Migratory, Proposed Endangered, Proposed Threatened, and Resident. The 'Extinct' option is currently selected. To the right of the dropdown, there are 'X' and '+' icons. Below the filter configuration, there are tabs for 'DATA', 'RESULTS', and 'SQL'. The 'SQL' tab is active, showing a SQL query. At the bottom right, there is a 'Row Limit' set to '500' and a 'Totals' checkbox.

```
SELECT
  parks.State AS parks_s,
  COUNT(DISTINCT CASE WHEN
    THEN (RIGHT(species.Speci
    species_changeable_co
  FROM biodiversity_in_parks.parks AS parks
  LEFT JOIN biodiversity_in_parks.species AS species ON parks.Park_Name = species
    .Park_Name

GROUP BY 1
ORDER BY 2 DESC
LIMIT 500
```

# Step 3

Value Inserted into SQL & New Query Run

The screenshot shows a SQL query editor with a filter dropdown menu open. The filter is set to "is equal to" and the dropdown menu lists the following conservation statuses: Breeder, Endangered, Extinct, In Recovery, Migratory, Proposed Endangered, Proposed Threatened, and Resident. The "Extinct" option is currently selected. The SQL query in the editor is as follows:

```
SELECT
  parks.State AS parks_s
  COUNT(DISTINCT CASE WHEN
  THEN (RIGHT(species.Speci
  species_changeable_co
FROM biodiversity_in_parks.parks AS parks
LEFT JOIN biodiversity_in_parks.species AS species ON parks.Park_Name = species
.Park_Name

GROUP BY 1
ORDER BY 2 DESC
LIMIT 500
```

# Step 4

Explore is Returned

Step 4

5,000 rows · from cache · 28m ago Run ⚙

▼ FILTERS (1) ■ Custom Filter

⚙ Species **Field to Select**   ×

# Templated Filters

How does the profit margin of the Jeans category compare to the profit margin across all other categories?

The screenshot shows a data query interface with a filter applied. The filter is for 'Products Choose A Category to Compare' with the value 'Jeans'. The results table shows the profit margin for 'Jeans' (48.17%) and 'All Other Categories' (52.96%).

| Products Category Comparator |                      | Order Items Profit Margin |
|------------------------------|----------------------|---------------------------|
| 1                            | Jeans                | 48.17%                    |
| 2                            | All Other Categories | 52.96%                    |

# Templated Filters

Example: LookML Input Logic

**Suggest Explore:** the Explore that will be queried in order to pull a list of suggested filter values

**Suggest Dimension:** the dimension that should be used within the suggest Explore for providing a list of suggested filter value

```
filter: choose_a_category_to_compare {  
  type: string  
  suggest_explore: inventory_items  
  suggest_dimension: products.category  
}
```

# Templated Filters

Example: Dynamic Dimension

```
dimension: category_comparator {  
  type: string  
  sql:  
    CASE WHEN  
      {% condition choose_a_category_to_compare %}  
        ${category}  
      {% endcondition %}  
    THEN ${category}  
    ELSE 'All Other Categories'  
  END  
  ;;  
}
```

# Templated Filters

▼ FILTERS (1) Custom Filter

GROUP BY 1
ORDER BY 1 DESC
LIMIT 500
```

# When to Use Parameters vs. Templated Filters

## Parameter Fields

- Insert user input directly (or using values you define as allowed values)

## Templated Filters

- Insert values as Looker-generated logical statements

# Caching & Datagroups

# Why cache?

Using **cached** results of prior queries helps to reduce database load

If you ETL new data into your database **every 12 hours**, your caching policy in Looker should reflect this

# How Caching Works in Looker

A **query** is run by a user and cached (cache results are stored in an encrypted file on the Looker instance)

# How Caching Works in Looker

500 rows · 6.7s · just now

Run

**A new query**

500 rows · from cache · just now

Run

**A cached query**

# How Caching Works in Looker

For any new queries, the cache is checked to see if the same query was previously run before running the query against the database

If the query is not found, Looker runs the query against the database and caches the new result

If the query is found and the results are still valid then Looker uses the cached results

If the query is found and the results are no longer valid, Looker runs the query against the database and caches the new result

# Implementing Caching in Looker

These caching policies can then be applied to various Looker objects:

- At the **model** or **Explore** level: use `persist_with` parameter to specify which Explores use each policy for clearing the query cache
- In a **PDT** definition: use `datagroup_trigger` to specify which policy to use in rebuilding the PDT
- On **Looks** and **dashboards**: build schedules that trigger based on datagroups to cause content to run and send immediately after the cache has been invalidated, thus warming the cache with the latest results

# Datagroups

**WHAT:** Named **caching policies** within Looker that can be applied to models, Explores, or Persistent Derived Tables

**WHY:** Integrate Looker more closely with ETL processes or guarantee a refreshed cache

- Define one or more datagroup parameters at the model level
- Different caching policies require separate datagroup definitions

# Configuring Datagroups

Caching policy parameters:

- **sql\_trigger** parameter
  - Should be SQL query that returns one row with one column
  - Typically will query a field that serves as a good indicator that the underlying data has been updated, such as a max(date) or will return a specific time of day
- **max\_cache\_age** to indicate the longest amount of time in which a query should be cached before being invalidated
- Only one of these parameters is required, but both are recommended

```
datagroup: daily_etl {  
  max_cache_age: "24 hours"  
  sql_trigger: SELECT max(id) FROM my_tablename ;;  
}
```

# Applying Datagroups to Query Results

A datagroup's caching policy can be applied to one, some or all Explores in a model.

- As a default for all Explores in a model: use the `persist_with` parameter at the model level and specify the name of the datagroup
- For a specific Explore: use the `persist_with` parameter in that Explore's definition and specify the name of the datagroup
- For a group of Explores: use the `persist_with` parameter in each Explore's definition and specify the name of the same datagroup

# Applying Datagroups to Query Results

Datagroups can also be used to add persistence to derived tables, [which will be covered in the next section](#)

| ecommerce_data.model ▼ |                              |
|------------------------|------------------------------|
| 1                      | connection: "thelook_events" |
| 2                      | persist_with: order_items    |
| 3                      |                              |

```
explore: order_items {
  persist_with: order_items
  join: users {
    type: left_outer
    sql_on: ${order_items.user_id} = ${users.id} ;;
    relationship: many_to_one
  }
}
```

## Datagroup example

```
datagroup: orders_datagroup {  
  sql_trigger: SELECT max(id) FROM my_tablename ;;  
  max_cache_age: "24 hours"  
  label: "ETL ID added"  
  description: "Triggered when new ID is added to ETL  
log"  
}
```

**Can be added to a model, explore, etc.**

# Monitoring Datagroups

Datagroups

| Database | Name  | Label        | Connection     | Model                | Type        | Description                               | Actions  |

# Derived Tables

# Going beyond the tables in your database

By default, Looker generates views from tables that already exist in your database.

```
LookML
order_items.view Table in your database
1 view: order_items {
2   sql_table_name: public.order_items ;;
3
4   dimension: order_item_id {
5     primary_key: yes
6     type: number
7     sql: ${TABLE}.id ;;
8   }
9
```

```
Generated SQL
DATA RESULTS SQL
SELECT
  order_items.order_id AS "order_items.order_id",
  COALESCE(SUM(order_items.sale_price ), 0) AS "order_item
FROM public.order_items AS order_items

GROUP BY 1
ORDER BY 2 DESC
LIMIT 500 Table in your database
```

# Going beyond the tables in your database

Sometimes in SQL, you need will want to create new tables, or sub-selects. In SQL terms, these can be known as ...

- Temporary tables or materialized views
- CTEs
- Subqueries

# Multi-step Aggregations

This will fail...

```
SELECT MAX(SUM(sales ) )  
FROM orders  
GROUP BY department
```

Fix by aggregating and grouping in multiple steps with a subquery:

```
SELECT MAX(subquery.total_sales )  
FROM  
    (SELECT SUM(sales) as total_sales  
     FROM orders  
     GROUP BY department) AS subquery
```

---

Example:

Which department has the highest total sales?

1. Find the total sales by department
2. Find the maximum of those totals

# Derived Tables Can Help!

You may want more flexibility to **restructure data** and **define complex query logic** to do cool things like...

- **Pre-aggregate** fields to aggregate aggregates
- **Utilize window functions** to sessionalize event data
- **Roll up user data** to the month level to track periods of (in)activity and analyze retention
- **Union** different marketing channels' tables so that KPIs are standardized and aggregated across the channels

# What Are Derived Tables?

Manually written query whose result set can be [queried like a regular database table](#)

Integrated into Looker as [views](#)

Can be [joined into Explores](#) just like standard views

They can be ephemeral or written into the database (PDT)

# Two Types of Derived Tables

---

## SQL Derived Table

- Easy to learn
- Easy to understand
- Uses complex joins, calculations and functions such as UNION

---

## Native Derived Table

- Maximum code reusability
- Easier to maintain
- Easier to read and understand

# SQL Derived Tables

# Step 1 Build / Test Query in SQL Runner

The screenshot displays the Looker SQL Runner interface. At the top, a blue banner indicates "You are in Development Mode." with an "Exit Development Mode" link on the right. Below this is a navigation bar with the Looker logo and menu items: "Browse", "Explore", "Develop", and "Admin". On the right side of the navigation bar are icons for search, home, help, and user profile.

The main heading is "SQL Runner" with a "Run" button and a settings gear icon to its right. The interface is divided into two main sections:

- Left Panel:** Contains configuration options. At the top are tabs for "Database", "Model", and "History". Below these are sections for "Connection" (set to "events\_ecommerce"), "Schema" (set to "public"), and "Tables". A search box "Search this schema" is present. The "Tables" list includes: distribution\_centers, etl\_jobs, events, foo, inventory\_items, order\_items, products, and users.
- Right Panel:** Shows the query editor. It has a "Visualization" tab (collapsed) and a "Results" tab (collapsed). The active "Query" tab is highlighted in dark grey and shows the text "Amazon Redshift". The SQL query is:

```
SELECT
  order_items.order_id,
  order_items.user_id,
  count(*) as order_item_count,
  sum(order_items.sale_price) as order_total
FROM order_items
GROUP BY 1,2
ORDER BY 3 DESC
LIMIT 50
```

## Step 2 Add Query into your LookML Project

The screenshot shows the Looker SQL Runner interface. At the top, a blue banner reads "You are in Development Mode." and "Exit Development Mode". Below this is a navigation bar with "Looker" logo and menu items: "Browse", "Explore", "Develop", and "Admin". On the right of the navigation bar are icons for search, home, help, and user profile. The main header is "SQL Runner" with a "Run" button and a settings gear icon (highlighted with a yellow box). The left sidebar contains tabs for "Database", "Model", and "History". Under "Database", there are sections for "Connection" (set to "events\_ecommerce"), "Schema" (set to "public"), and "Tables" (listing "distribution\_centers", "etl\_jobs", "events", "foo", "inventory\_items", "order\_items", "products", "users"). The main area shows a SQL query editor with a context menu open over the "Query" tab. The menu items are: "Download...", "Add to Project..." (highlighted with a yellow box), "Get Derived Table LookML...", "Get LookML Generated From SQL...", "Explore", and "Clear".

# Step 3 Name your New View

The screenshot shows the Looker SQL Runner interface. At the top, a blue bar indicates "You are in Development Mode." and "Exit Development Mode". Below this is a navigation bar with "Looker" and menu items "Browse", "Explore", "Develop", and "Admin". The main area is titled "SQL Runner" and contains a "Run" button and a settings gear icon. A modal dialog box titled "Add to Project" is open, featuring two input fields: "Project" with the value "ecommerce" and "View Name" with the value "sql\_runner\_query". At the bottom of the dialog are "Cancel" and "Add" buttons. The background shows a list of database tables including "inventory\_items", "order\_items", "products", and "users".

# Step 4

## Review & Clean Up Your View

Looker creates a new view with the SQL Runner query and will write dimensions for every field as well as a count measure:

The screenshot shows the Looker interface in Development Mode. The top navigation bar includes 'Looker', 'Browse', 'Explore', 'Develop', and 'Admin'. The main content area is titled 'ecommerce' and shows a 'File Browser' on the left with a list of views. The 'order\_facts\_sql\_runner.view' is selected and highlighted. The right pane displays the view's configuration, including a SQL query and LookML definitions for measures and dimensions.

```
1 view: order_facts_sql_runner {
2   derived_table: {
3     sql: SELECT
4       order_items.order_id,
5       order_items.user_id,
6       count(*) as order_item_count,
7       sum(order_items.sale_price) as order_total
8     FROM order_items
9     GROUP BY 1,2
10    ORDER BY 3 DESC
11    LIMIT 50
12    ;;
13  }
14 }
15
16 measure: count {
17   type: count
18   drill_fields: [detail*]
19 }
20
21 dimension: order_id {
22   type: number
23   sql: ${TABLE}.order_id ;;
24 }
25
26 dimension: user_id {
27   type: number
28   sql: ${TABLE}.user_id ;;
29 }
30
31 dimension: order_item_count {
32   type: number
33   sql: ${TABLE}.order_item_count ;;
34 }
35
36 dimension: order_total {
37   type: number
38   sql: ${TABLE}.order_total ;;
39 }
40
41 set: detail {
42   fields: [order_id, user_id, order_item_count, order_total]
43 }
```

# Best Practice: 5 Steps for Success

After creating your shiny new derived table:

1. Move the view file to the appropriate **folder**
2. Erase any **LIMIT** in the SQL
3. Remove or hide the **count** measure
4. Establish the **primary key**
5. Write the desired **measures** and any additional dimensions

# Native Derived Tables

# Maximizing Code Reusability

The SQL for the User Facts table just built included the following definitions:

- COUNT(distinct order\_items.order\_id) as lifetime\_order\_count
- SUM(order\_items.sale\_price) as lifetime\_revenue

```
measure: order_count {  
  description: "A count of unique orders"  
  type: count_distinct  
  sql: ${order_id} ;;  
}
```

```
measure: total_revenue {  
  type: sum  
  value_format_name: usd  
  sql: ${sale_price} ;;  
  drill_fields: [detail*]  
}
```

**BUT WAIT!** These measures were already defined within the LookML in the order\_items view

# Native Derived Tables

How can we take advantage of dimensions and measures that have already been defined within the LookML?

Native Derived Tables are derived tables that perform the same function as a written SQL query, but are expressed natively in the LookML language

- Easier to read and understand when modeling data
- Enables code to be reused
- More maintainable since physical database references are minimized

# Step 2 Select Get LookML

The screenshot shows the Looker 'Explore' interface. The top navigation bar includes 'Browse', 'Explore', 'Develop', and 'Admin'. The main header displays 'Explore', '500 rows · 4.5s · just now', and a 'Run' button. A settings gear icon is highlighted with a yellow box. A dropdown menu is open, listing various actions: 'Save as a Look...', 'Save to Dashboard...', 'Download...', 'Send...', 'Save & Schedule...', 'Share...', 'Get LookML...', 'Merge Results...', 'Remove Fields & Filters', and 'Clear Cache & Refresh'. The 'Get LookML...' option is highlighted with a yellow box. The background shows a table with columns 'Order Items User ID' and 'Order Items To'.

| Order Items User ID | Order Items To |
|---------------------|----------------|
| 1                   | 2924           |
| 2                   | 9996           |
| 3                   | 16536          |
| 4                   | 278            |
| 5                   | 26618          |
| 6                   | 425            |
| 7                   | 56217          |
| 8                   | 10752          |
| 9                   | 32972          |
| 10                  | 56528          |
| 11                  | 16304          |
| 12                  | 5634           |
| 13                  | 11581          |
| 14                  | 7617           |
| 15                  | 3902           |
| 16                  | 12130          |
| 17                  | 2200           |
| 18                  | 6881           |
| 19                  | 362            |

# Step 3 Copy the Derived Table LookML

The screenshot shows the Looker interface with a 'Get LookML' dialog box open. The dialog has three tabs: 'Dashboard', 'Aggregate Table', and 'Derived Table', with 'Derived Table' selected. The dialog contains the following text:

Copy the LookML code below, and paste it into your project definition.

```
# If necessary, uncomment the line below to include explore_source.  
# include: "ecommerce_neat.model.lkml"  
  
view: add_a_unique_name_1610665100 {  
  derived_table: {  
    explore_source: order_items {  
      column: user_id {}  
      column: total_sales {}  
      column: count {}  
    }  
  }  
  dimension: user_id {  
    description: "A unique identification number for an individual  
customer"  
    type: number  
  }  
  dimension: total_sales {  
    value_format: "$#,##0.00"  
    type: number  
  }  
  dimension: count {  
    label: "Order Items Order Item Count"  
  }  
}
```

The background shows the 'Explore' view for 'Orders and Revenue' with a search bar and a list of fields under 'All Fields'. The 'Order Items' section is expanded, showing dimensions like 'Created Date', 'Delivered Date', 'Delivery Time', 'Order ID', 'Order Status', 'Returned Date', 'Sale Price', 'Sale Price Tier', and 'Shipped Date', and measures like 'Average Sales' and 'Order Count'. A table with columns for 'Count' and 'Totals' is visible on the right.

# Native Derived Table Parameters

## explore\_source:

the Explore defined within Looker that contains the field and join definitions required for the desired query

## column:

specifies an output column for the derived table

- often paired with a “field” parameter to link the new table column back to the appropriate underlying column
- can be named differently from the underlying field referenced

## filters:

can be used for applying filters to the derived table using the same syntax as a filtered measure

# Native Derived Table Parameters

## `derived_column:`

specify one or more columns that don't exist in the Explore specified by the `explore_source` parameter

## `bind_filters:`

used for applying templated filters to the native derived table

## `expression_custom_filter:`

specify one or more custom filter expressions on an `explore_source` query

# Persistent Derived Tables

# Persistent Derived Tables

Add two (2) parameters to a derived table when persisting it:

1. Table refresh logic for table rebuilding
  - a. **datagroup\_trigger**: triggered by some change that takes place in the underlying data as defined within a datagroup
  - b. **sql\_trigger\_value**: triggered by a change in the underlying data
  - c. **persist\_for**: a set time period
2. Indexes
  - a. A single or multiple index for most databases
  - b. Sort key(s) and a distribution key for Redshift
  - c. Cluster key(s) and partition key(s) for BigQuery

# Ephemeral vs. Persistent Derived Tables

Ephemeral derived tables will build at runtime as a temporary table (mysql) or via a SQL common table expression

```
WITH user_order_facts AS (SELECT
  order_items.user_id as user_id
  , COUNT(DISTINCT order_items.order_id) as lifetime_orders
  , SUM(order_items.sale_price) AS lifetime_revenue
  , MIN(NULLIF(order_items.created_at,0)) as first_order
  , MAX(NULLIF(order_items.created_at,0)) as latest_order
  , COUNT(DISTINCT DATE_TRUNC('month', NULLIF(order_items.created_at,0))) as number_of_distinct_months_with_orders
  , SUM(order_items.sale_price) AS order_value
FROM order_items
GROUP BY user_id
```

Derived Table SQL

```
)
SELECT
  user_order_facts.lifetime_orders AS "user_order_facts.lifetime_orders",
  COUNT(DISTINCT order_items.order_id) AS "order_items.order_count"
FROM public.order_items AS order_items
LEFT JOIN user_order_facts ON user_order_facts.user_id = order_items.user_id

GROUP BY 1
ORDER BY 2 DESC
LIMIT 500
```

Explore SQL

# Ephemeral vs. Persistent Derived Tables

Persistent derived tables will be stored as physical tables within the database once built. Looker will then simply query those physical tables as needed. Looker will build separate PDTs in development and production modes

```
-- use existing user_order_facts in teach_scratch.LR$KDYI2NQM4DW046XHR9XQH_user_order_facts
SELECT
  user_order_facts.lifetime_orders AS "user_order_facts.lifetime_orders",
  COUNT(DISTINCT order_items.order_id ) AS "order_items.order_count"
FROM public.order_items AS order_items
LEFT JOIN teach_scratch.LR$KDYI2NQM4DW046XHR9XQH_user_order_facts AS user_order_facts ON user_order_facts.user_id = order_items
  .user_id

GROUP BY 1
ORDER BY 2 DESC
LIMIT 500
```

# Summary

## Derived Tables

**WHAT:** Tables defined within Looker that do not exist in the database

- Two types of derived tables
  - Ephemeral: built at query time
  - Persisted: stored in the database
- Two ways to write derived tables
  - SQL
  - Native (using LookML)
- Defined within the LookML
- Referenced in the LookML just like any other table

# Summary

## Derived Tables

**WHY:** Expand the sophistication of analyses

- Aggregate data to a different level of granularity (*ex: aggregate fact data*)
- Speed up performance (*ex: precompute joins*)
- Write custom SQL for advanced use cases (*ex: utilize window functions*)

# Questions?

## Q&A from the audience:

**Q:** When using links, to create them available to just a particular context, I've been creating a new dimension with a unique name, including in a report, and then hiding the field. Is there a better way to manage dimensions that vary only by the link?

**A:** It sounds like this could be a good use case for some liquid conditional statements! Not knowing your particular use case, let's assume we have user attributes for different departments (A, B, C, etc), and each department needs its own unique link for the dimension. To accomplish this, we would use the following pattern for as many departments as needed:

```
dimension: multiple_links {
  type: string
  sql: ${TABLE}.field_name
  html:
    {% if _user_attributes['department'] == 'Department A' %}
      <a href="www.link-for-department-a"> Link text </a>
    {% elsif _user_attributes['department'] == 'Department B' %}
      <a href="www.link-for-department-b"> Link text </a>
    ... etc
    {% endif %};;
}
```

## Q&A from the audience:

**Q:** Will New UI Dashboards support drilling to dashboards?

**A:** **Drilling improvements are slated for the new dashboard experience, but no details are available at the moment. If drilling to dashboards is something you'd like to see, I highly recommend creating a feature request in our Community (community.looker.com).**

**Q:** Can you pass more than one filter to a dashboard using liquid?

**A:** **Yes! You can pass multiple filters in using liquid. As long as the dashboard you are drilling to has filters created on it, use the following pattern:**

```
dimension: dimension_name {
  type: string
  sql: ${TABLE}.field_name ;;
  html:
    <a href="/dashboards/dashboardnumber?Filter1={{ value }}&Filter2={{ field2_name._value}}">
      {{ value }}
    </a> ;;
}
```

## Q&A from the audience:

**Q:** What is the difference between `encode_uri` vs `encode_url`?

**A:** Both tags will encode strings so they function correctly in a link. `encode_url` is the tag created for base liquid by Shopify while `encode_uri` is unique to Looker.

**Q:** Does the filter that you use in the URL for liquid have to be saved as part of the target dashboard? What if dashboard 24 doesn't have a "Brand" filter at the top?

**A:** The target Dashboard needs to have a filter created on it that matches the name of the filter in the link.

```
/dashboards/24?Brand={{ value | encode_uri }}
```

Names must match

## Q&A from the audience:

**Q:** So a LookML with this link URL Code is coded in the LookML. What if I have a dashboard where I don't want a link on the Dimension Brand Do I have to refer to a different LookML Code?

**A:** Currently there is not a way to have the Brand dimension display or hide a link at the Dashboard level, but you can control if a link is shown based on which Explore the Brand dimension is a part of. Let's say we have two Explores, Yeslinks and Nolinks. We could use the following patterns to shown links on the Brand dimension in the Yeslinks Explore, and hide links in the Nolinks Explore.

```
dimension: brand {
  type: string
  sql: ${TABLE}.string
  html:
    {% if _explore._name == 'Yeslinks' %}
      <a href="/dashboards/24?Brand={{ value | encode_uri }}"> Link text </a>
    {% else %}
      {{ value }}
    {% endif %};;
}
```

## Q&A from the audience:

**Q:** For something like the salesforce link example, is it best practice to use html or link (if not doing much customization to the link)?

**A:** It mainly depends on how you want your link to appear to the user.

| Products ID Link ^ | Products ID HTML |
|--------------------|------------------|
| 1                  | 1                |
| 2                  | 2                |
| 3                  | 3                |
| 4                  | 4                |
| 5                  | 5                |
| 6                  | 6                |

Using `link: {}` creates a menu to access the links

Using `html:` makes the values clickable links

## Q&A from the audience:

**Q:** For which user permissions is drilling available?

**A:** A user will need the `see_drill_overlay` permission to see drills.

**Q:** How do you make the custom drill with html open in a new tab?

**A:** Adding `target="_blank"` to a link will cause it to open in a new tab or browser window, depending on the user's browser settings.

```
<a href="/dashboards/24?Brand={{ value | encode_uri }}" target="_blank"> Link text </a>
```

**Q:** This custom drilling will show as a pop up? like the normal drill?

**A:** The example with user item and order history opens in a new window. It is also possible to customize drill menus with liquid, please check out our Help Center Article "[More Powerful Data Drilling](#)".

## Q&A from the audience:

**Q:** If you're referencing a different field in a custom drill (like ID instead of name), does the relationship between the field clicked and the field referenced need to be 1:1?

**A: Yes**

**Q:** Can this conditional formatting be applied also on the second column in your example?

**A: I believe this is referring to the example of custom colored bars using html, in which case the answer would be yes. Formatting using liquid and html can be applied to both dimensions and measures.**

**Q:** What's the best resource for learning more about liquid syntax and potential applications of it?

**A: I highly recommend reading our [Liquid Variable Reference Looker documentation](#) for syntax help and examples of using liquid in Looker. Additionally, searching our Help Center ([help.looker.com](http://help.looker.com)) and Community ([community.looker.com](http://community.looker.com)) for Liquid will produce a treasure trove of examples and applications.**

**Q:** Can I use a parameter to set the colors?

**A: Yes! We have an example of using a parameter to change colors in [our Documentation](#).**

## Q&A from the audience:

**Q:** Does Looker accept HTML5?

**A:** For security, Looker only accepts certain sanitized HTML. You can find the allowed HTML in [our Documentation](#).

**Q:** What's `_linked_value`?

**A:** `linked_value` is the value of the field with Looker's default formatting and default linking.

**Q:** How the Total Gross Margin example looks like in the graph?

**A:** In the example showing the Total Gross Margin with a drop-down detail of the values that compose it, the results must be visualized as a table visualization for the HTML customization to work. Other visualization types will not correctly display the drop-down.

## Q&A from the audience:

**Q:** On that last example - if you pull into multiple numbers into a single tile, how does that affect dashboard load times?

**A:** Because we are rendering more data in a single visualization, it take additional resources for the browser to load than a standard single value visualization. However, dashboard performance impact should be negligible.

**Q:** What is the LookML code (liquid) of the last viz?

**A:** You can find the LookML code for the colorful single value visualization in this [Community post](#).

## Q&A from the audience:

**Q:** Question about the advanced single viz html formatting: the code for icons references a html "fa" class (eg. fa fa-facebook; fa fa-leaf). does this mean that looker has imported the Font Awesome CSS library in the background? thanks

**A: Yes, Looker uses Font Awesome v4.1.0.**

## Q&A from the audience:

**Q:** Can I build a parameter/suggestion field? Parameters have value & label, which would be tremendous for users to pick a friendly label and pass an ID in the value.

**A:** **This sounds like a templated filter may be better suited to this use case. While parameters require users to choose from a predetermined value, templated filters allow users to input a much wider range of values and filter options.**

**Q:** Can a parameter be used to filter the options available for another filter? Like we can do with dashboard filters

**A:** **Not currently, but this sounds like an excellent idea for a [feature request](#)!**

**Q:** Is it possible to link two different liquid filters from two different views (both joined to the same explore) to the same Dashboard filter?

**A:** **Yes, provided the filter on the dashboard matches the filter name in the URL being used in the liquid.**

## Q&A from the audience:

**Q:** Does the level of detail also work for the dimension\_group date? For example if I want to go from day to hour, would I be able to do that?

**A:** Yes, you can reference different parts of a dimension group to change the granularity of time. This [Help Center article](#) has an example of using parameters to change the granularity of time.

**Q:** is there a way to select multiple options from a parameter or input a value?

**A:** A parameter takes a single input, for multiple inputs you will want to use a templated filter.

**Q:** Does this mean that Brand becomes the default value if the user doesn't click to select something else?

**A:** Correct, because we set a default value of “Brand” this is the level of granularity that will be used if a user does not select anything.

## Q&A from the audience:

**Q:** How do I insert a parameter value in the sql: block of a derived table?

**A:** Parameters and liquid can be referenced in the SQL block of a derived table. To see all of the places the parameter liquid variable can be used, please see [our documentation](#).

**Q:** How can I create a filter in LookMLs to filter information by "User Logged". Eg: I want to display on a dashboard, only sales done by the User's Team (Assuming there is a Team Table with Manager's name)

**A:** This is an excellent use case for [User Attributes](#)! We have a [Help Center article](#) that walks through this very use case.

**Q:** Are these templated filters usable as page filter too, or only within a look?

**A:** Templated filters can be used on Explore, Looks, and Dashboards.

## Q&A from the audience:

Q: why a templated filter is better than using a dimension as a filter?

**A: Standard Looker filters created from dimensions affect the WHERE clause of the generated SQL, and therefore apply to all fields in the query. Templated filters can be applied directly to fields in the SELECT clause of the generated SQL, opening up a world of advanced filtering and comparison capabilities.**

Q: All the example for templated filters shows a drop down style? Will it be possible to do check box, button bars slider style filters?

**A: The example shown were on an Explore, which only uses a drop down style. Templated filter can also be used on a Dashboard where more filtering options are available.**

Q: Do other filters apply to the templated filters? let's say comparing jeans vs other categories in a certain geographical area

**A: Yes! Standard Looker filters created from dimensions affect the WHERE clause of the generated SQL, and therefore apply to all fields in the query**

## Q&A from the audience:

**Q:** Can you use templated filters and parameters on dashboards?

**A:** Yes!

**Q:** Is the query only cached for the initial 500 results?

**A:** The query is cached for all of the returned results. If you have 5000 results then 5000 rows will be cached.

**Q:** Should we expect questions like these for lookML developer certification?

**A:** Topics such as derived tables and caching are included in the Exam Guide for the LookML Developer certification exam, and therefore are fair game. For a list of topics to study please check out our [Exam Guides](#).

**Q:** How do we set cache for dashboard or Looks

**A:** To set a cache for a dashboard or Look, you want to create a caching policy for the model or Explore that provides the data on the dashboard.

## Q&A from the audience:

**Q:** If an Explore contains three tables with different ETL timings, how do you refresh the cache whenever any of the three tables updates?

**A:** You will want to create a datagroup trigger that reflects the table that updates the most frequently, and then apply that datagroup to any Explores you want updated.

**Q:** Why do we need trigger and cache age both

**A:** Although only one of these two options is required, we recommend using both when creating a datagroup. For example, the `max_cache_age` parameter ensures that if the cache for a datagroup isn't cleared by the `sql_trigger`, then the cache entries will expire by a certain time.

**Q:** Can we have data groups based on etl triggers like control M and other scheduling tools that will send inputs or cache cubes based on file drop?

**A:** The `sql_trigger` for a datagroup must be derived from a value that can be calculated in the database you have connected to Looker.

# Q&A from the audience:

**Q:** Can you explain what is symmetric aggregation?

**A:** Lloyd Tabb has a wonderful explanation of [symmetric aggregation](#) in our Help Center.

**Q:** How do i best join dimension/measures from derived table back to another view? it seems like when i try to do this, the query runs for along time. Any tips?

**A:** You may want to double-check that you have the [correct join relationship](#) between your derived table and your view. Additionally, all views should have unique primary keys defined. Derived tables should have indexes and sort keys defined. For additional optimization tips, check out this [Help Center article](#).

## Q&A from the audience:

**Q:** From your experience what is the best way to build a histogram like visualization as it doesn't seem to be native in Looker. I know step 1 is derived table, but how would I get the "bucketing"?

**A:** Depending on what you are bucketing, the first step may indeed be to create a derived table so that you can calculate your aggregate and then reference it as a dimension in Looker. Once you have done that, the next step will be to create a tier dimension to bucket those values into the ranges you desire. This [Help Center article](#) can walk you through these steps. Also, if you are using custom visualizations in the Looker Marketplace, you may be interested to know that a [histogram visualization](#) was recently added!

**Q:** Are PDT created as a new view within the model?

**A:** If you are following the steps to create a derived table from SQL Runner or and Explore then yes, the derived table will be added as a new view within the model.

**Thank you**
